Abstract

After the first treatments of quantum finite state automata by Moore and Crutchfield and by Kondacs and Watrous, a number of papers study the power of quantum finite state automata and their variants. This paper introduces a model of two-way quantum one-counter automata (2Q1CAs), combining the model of two-way quantum finite state automata (2QFAs) by Kondacs and Watrous and the model of one-way quantum one-counter automata (1Q1CAs) by Kravtsev. We give the definition of 2Q1CAs with well-formedness conditions. It is proved that 2Q1CAs are at least as powerful as classical two-way deterministic one-counter automata (2D1CAs), that is, every language L recognizable by 2D1CAs is recognized by 2Q1CAs with no error. It is also shown that several non-context-free languages including $\{a^n b^{n^2} \mid n \geq 1\}$ and $\{a^n b^{2^n} \mid n \geq 1\}$ are recognizable by 2Q1CAs with bounded error.

1 Introduction

Quantum finite state automata were introduced by Moore and Crutchfield [19] and Kondacs and Watrous [15] independently. In particular, the latter introduced both of the quantum counterparts of one-way and two-way finite state automata, which are called one-way and two-way quantum finite state automata (1QFAs and 2QFAs), respectively. In the classical case, it is well known that two-way deterministic finite state automata (2DFAs) remain the same in view of language recognition as one-way deterministic finite state automata (1DFAs), and both of the class of languages recognized by 1DFAs and 2DFAs are exactly the class of regular languages. In the quantum case, the situation becomes different. In fact, Kondacs and Watrous [15] showed that the class of languages recognized by 1QFAs is properly contained in the class of regular languages, while that of 2QFAs properly contains the class of regular languages. Subsequently, a number of papers study the power of quantum finite state automata [7, 2, 8, 11, 3, 20, 1, 6, 5] and their variants [4, 9, 16, 21, 14, 10, 13].

As for the counter automata, Kravtsev [16] introduced a quantum version of one-way one-counter automata (one-way quantum one-counter automata, 1Q1CAs). In the classical case, it can be easily seen that the class of languages recognized by one-way deterministic one-counter automata (1D1CAs) is properly contained in the class of context-free languages (CFL), because 1D1CAs are the special case of one-way pushdown automata (1PDAs) and the class of languages recognized by 1PDAs is equal to that of CFL. Kravtsev showed that some non-regular languages and some non-context-free languages are recognized by 1Q1CAs with bounded error, which means, in some cases, 1Q1CAs are more powerful than the classical counterparts. A consecutive work by Yamasaki, Kobayashi, Tokunaga, and Imai [21] showed that these non-regular or non-context-free languages are also recognized by one-way probabilistic reversible one-counter automata (1PR1CAs) with bounded error. They also

showed that there exists a regular language which cannot be recognized by bounded error 1Q1CAs, which means that, in some cases, 1Q1CAs are less powerful than the classical counterparts. Recently Bonner, Freivalds, and Kravtsev [10] showed that there exists a language which cannot be recognized by one-way probabilistic one-counter automata (1P1CAs) with bounded error, but can be recongnized by bounded error 1Q1CAs.

In one-way case, the automaton can read each symbol of an input only once. This can be regarded as a quite strong restriction for quantum cases, because each step of evolution of quantum automata should be unitary. If this restriction of one-way is removed, how much power is added to quantum one-counter automata? From this point of view, this paper introduces two-way quantum one-counter automata (2Q1CAs) and analyzes the power of this model. We give a formal definition of 2Q1CAs with well-formedness conditions, and compare the power of 2Q1CAs with that of two-way deterministic one-counter automata (2D1CAs). It is shown that if a language L is recognized by 2D1CAs, L is necessarily recognized by 2Q1CAs with no error, which means that 2Q1CAs are at least as powerful as 2D1CAs. It is also shown that bounded error 2Q1CAs can recognize some non-context-free languages such as $\{a^n b^{n^2} \mid n \geq 1\}$, $\{a^m b^n c^{mn} \mid m, n \geq 1\}$, $\{a^n b^{2^n} \mid n \geq 1\}$, and so on. These languages do not seem to be recognized by 2D1CAs, therefore, the authors conjecture that 2Q1CAs are strictly more powerful than 2D1CAs.

The remainder of this paper is organized as follows. In Section 2 we give a formal definition of 2Q1CAs with well-formedness conditions and introduce the concept of simple 2Q1CAs. In Section 3, using the technique of reversible simulation, we prove that if a language L is recognized by 2D1CAs, L is necessarily recognized by 2Q1CAs with no error. In Section 4, we show that 2Q1CAs can recognize some non-context-free languages with bounded error. Finally we conclude with Section 5, which summarizes our results and mentions several open problems.

2 Definitions

2.1 Two-way One-counter Automata

Here we give formal definitions of two-way one-counter automata both in classical and quantum cases. First we define two-way deterministic one-counter automata.

Definition 1 *A two-way deterministic one-counter automaton (2D1CA) is defined as* $M = (Q, \Sigma, \delta, q_0, Q_{\rm acc}, Q_{\rm rej})$*, where* Q *is a finite set of states,* Σ *is a finite input alphabet,* q_0 *is an initial state,* $Q_{\rm acc} \subset Q$ *is the set of accepting states,* $Q_{\rm rej} \subset Q$ *is the set of rejecting states, and* $\delta : Q \times \Gamma \times S \rightarrow Q \times \{-1, 0, +1\} \times \{\leftarrow, \downarrow, \rightarrow\}$ *is a transition function, where* $\Gamma = \Sigma \cup \{¢, \$\}$*, symbol* $¢ \notin \Sigma$ *is the left end-marker, symbol* $\$ \notin \Sigma$ *is the right end-marker, and* $S = \{0, 1\}$*.*

We assume that each 2D1CA has a counter which can contain an arbitrary integer. When δ returns $-1, 0, +1$, respectively, as the second element, the automaton decreases the counter value by 1, retains the same, and increases by 1. Let $s = \mathrm{sign}(k)$, where k is the counter value and $\mathrm{sign}(k) = 0$ if $k = 0$, otherwise 1.

We also assume that every input written on the tape is started by ¢ and terminated by \$, and that such a tape is circular. When δ returns $\leftarrow, \downarrow, \rightarrow$, respectively, as the third element, the automaton moves its tape head left by a square, remains stationary, and moves right by a square.

At the beginning of computation, the state is q_0, the counter value is 0, and the tape head is scanning the left-most symbol of an input. At each step, the automaton reads a symbol σ in the state q, checks whether the counter value is 0 or not (i.e. checks s), and finds an appropriate transition $\delta(q, \sigma, s) = (q', c, d)$, where $c \in \{-1, 0, +1\}$ and $d \in \{\leftarrow, \downarrow, \rightarrow\}$. Then it enters the state q', updates the counter value according to c, and moves its tape head in direction d. The automaton accepts the input if it enters the final state in $Q_{\rm acc}$ and rejects if it enters the final state in $Q_{\rm rej}$.

Next we define two-way quantum one-counter automata.

Definition 2 *A two-way quantum one-counter automaton (2Q1CA) is defined as* $M = (Q, \Sigma, \delta, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}})$*, where* $Q, \Sigma, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}}$ *are defined in the same manner as those with 2D1CAs. A transition function* δ *is defined as* $Q \times \Gamma \times S \times Q \times \{-1, 0, +1\} \times \{\leftarrow, \downarrow, \rightarrow\}$*, where* $\Gamma, \text{¢}, \$, S$ *are also defined in the same manner as those with 2D1CAs.*

The definition of a counter and a tape also remains the same as those with 2D1CAs.

For any $q_1, q_2 \in Q$, $\sigma, \sigma_1, \sigma_2 \in \Gamma$, $c \in \{-1, 0, +1\}$, $d \in \{\leftarrow, \downarrow, \rightarrow\}$, δ satisfies the following conditions (*well-formedness conditions*):

$$\sum_{q',c,d} \delta^*(q_1, \sigma, s, q', c, d)\delta(q_2, \sigma, s, q', c, d) = \begin{cases} 1 & q_1 = q_2, \\ 0 & q_1 \neq q_2, \end{cases} \tag{1}$$

$$\sum_{q',c} \Big(\delta^*(q_1, \sigma_1, s, q', c, \leftarrow)\delta(q_2, \sigma_2, s, q', c, \downarrow) + \delta^*(q_1, \sigma_1, s, q', c, \downarrow)\delta(q_2, \sigma_2, s, q', c, \rightarrow) \Big) = 0, \tag{2}$$

$$\sum_{q',c} \delta^*(q_1, \sigma_1, s, q', c, \leftarrow)\delta(q_2, \sigma_2, s, q', c, \rightarrow) = 0, \tag{3}$$

$$\sum_{q',d} \Big(\delta^*(q_1, \sigma, s_1, q', -1, d)\delta(q_2, \sigma, s_2, q', 0, d) + \delta^*(q_1, \sigma, s_1, q', 0, d)\delta(q_2, \sigma, s_2, q', +1, d) \Big) = 0, \tag{4}$$

$$\begin{aligned} \sum_{q'} \Big(& \delta^*(q_1, \sigma_1, s_1, q', -1, \leftarrow)\delta(q_2, \sigma_2, s_2, q', 0, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', -1, \downarrow)\delta(q_2, \sigma_2, s_2, q', 0, \rightarrow) \\ & + \delta^*(q_1, \sigma_1, s_1, q', 0, \leftarrow)\delta(q_2, \sigma_2, s_2, q', +1, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', 0, \downarrow)\delta(q_2, \sigma_2, s_2, q', +1, \rightarrow) \Big) = 0, \end{aligned} \tag{5}$$

$$\begin{aligned} \sum_{q'} \Big(& \delta^*(q_1, \sigma_1, s_1, q', -1, \rightarrow)\delta(q_2, \sigma_2, s_2, q', 0, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', -1, \downarrow)\delta(q_2, \sigma_2, s_2, q', 0, \leftarrow) \\ & + \delta^*(q_1, \sigma_1, s_1, q', 0, \rightarrow)\delta(q_2, \sigma_2, s_2, q', +1, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', 0, \downarrow)\delta(q_2, \sigma_2, s_2, q', +1, \leftarrow) \Big) = 0, \end{aligned} \tag{6}$$

$$\sum_{q'} \Big(\delta^*(q_1, \sigma_1, s_1, q', -1, \leftarrow)\delta(q_2, \sigma_2, s_2, q', 0, \rightarrow) + \delta^*(q_1, \sigma_1, s_1, q', 0, \leftarrow)\delta(q_2, \sigma_2, s_2, q', +1, \rightarrow) \Big) = 0, \tag{7}$$

$$\sum_{q'} \Big(\delta^*(q_1, \sigma_1, s_1, q', -1, \rightarrow)\delta(q_2, \sigma_2, s_2, q', 0, \leftarrow) + \delta^*(q_1, \sigma_1, s_1, q', 0, \rightarrow)\delta(q_2, \sigma_2, s_2, q', +1, \leftarrow) \Big) = 0, \tag{8}$$

$$\sum_{q',d} \delta^*(q_1, \sigma, s_1, q', -1, d)\delta(q_2, \sigma, s_2, q', +1, d) = 0, \tag{9}$$

$$\sum_{q'} \Big(\delta^*(q_1, \sigma_1, s_1, q', -1, \leftarrow)\delta(q_2, \sigma_2, s_2, q', +1, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', -1, \downarrow)\delta(q_2, \sigma_2, s_2, q', +1, \rightarrow) \Big) = 0, \tag{10}$$

$$\sum_{q'} \Big(\delta^*(q_1, \sigma_1, s_1, q', -1, \rightarrow)\delta(q_2, \sigma_2, s_2, q', +1, \downarrow) + \delta^*(q_1, \sigma_1, s_1, q', -1, \downarrow)\delta(q_2, \sigma_2, s_2, q', +1, \leftarrow) \Big) = 0, \tag{11}$$

$$\sum_{q'} \delta^*(q_1, \sigma_1, s_1, q', -1, \leftarrow)\delta(q_2, \sigma_2, s_2, q', +1, \rightarrow) = 0, \tag{12}$$

$$\sum_{q'} \delta^*(q_1, \sigma_1, s_1, q', -1, \rightarrow)\delta(q_2, \sigma_2, s_2, q', +1, \leftarrow) = 0. \tag{13}$$

A computation on an input x of length n corresponds to a unitary evolution in the Hilbert space $\mathcal{H}_n = l_2(C_n)$. For each $(q, a, b) \in C_n, q \in Q, a \in \mathbb{Z}, b \in [0, n+1]$, let $|q, a, b\rangle$ denote the basis vector in $l_2(C_n)$. An operator U_x^δ for an input x on $\mathcal{H}_n$ is defined as follows:

$$U_x^\delta \, |q, a, b\rangle = \sum_{q',c,d} \delta(q, w_x(b), \mathrm{sign}(a), q', c, d) \, \big|q', a + c, b + \mu(d)\big\rangle,$$

where $w_x(b)$ is the bth symbol of $w_x = \text{¢}x\$$ and $\mu(d) = -1(0)[+1]$ if $d = \leftarrow (\downarrow)[\rightarrow]$. We assume that this operator is unitary, that is, $\left(U_x^\delta\right)^* U_x^\delta = U_x^\delta \left(U_x^\delta\right)^* = I$.

After each transition, a state of a 2Q1CA is observed. A computational observable O corresponds to the orthogonal decomposition $l_2(C_n) = E_{\mathrm{acc}} \oplus E_{\mathrm{rej}} \oplus E_{\mathrm{non}}$. The outcome of any observation will be either "accept" (E_{acc}), "reject" (E_{rej}) or "non-halting" (E_{non}). The probability of acceptance, rejection, and non-halting at each step is equal to the sum of the squared amplitude of each basis state in the new state for the corresponding subspace. After the measurement, the state collapses to the projection to one of $E_{\mathrm{acc}}, E_{\mathrm{rej}}, E_{\mathrm{non}}$.

Definition 3 *A language L is recognizable by a 2Q1CA with probability p, if there exists a 2Q1CA M which accepts any input $x \in L$ with probability at least $p > 1/2$ and rejects any input $x \notin L$ with probability at least p.*

Finally we define two-way reversible one-counter automata, which can be regarded as a special case of 2Q1CAs.

Definition 4 *A two-way reversible one-counter automaton (2R1CA) is defined as a well-formed 2Q1CA whose transition amplitudes only take 0 and 1.*

Lemma 5 *A 2Q1CA satisfies the well-formedness conditions if and only if U_x^δ is a unitary operator.*

Proof. By the definition, U_x^δ transforms two quantum states $|q_1, a_1, b_1\rangle, |q_2, a_2, b_2\rangle$ into the following states:

$$\begin{aligned} U_x^\delta |q_1, a_1, b_1\rangle &= \sum_{q_1', c_1, d_1} \delta(q_1, \sigma_1, s_1, q_1', c_1, d_1) \left| q_1', a_1 + c_1, b_1 + \mu(d_1) \right\rangle, \\ U_x^\delta |q_2, a_2, b_2\rangle &= \sum_{q_2', c_2, d_2} \delta(q_2, \sigma_2, s_2, q_2', c_2, d_2) \left| q_2', a_2 + c_2, b_2 + \mu(d_2) \right\rangle. \end{aligned}$$

First, we assume that U_x^δ is a unitary operator, that is, $\left(U_x^\delta\right)^* U_x^\delta = I$. Then we have the inner product of the previous two vectors as follows:

$$\begin{aligned} &\langle q_1, a_1, b_1 \mid q_2, a_2, b_2\rangle = \left\langle q_1, a_1, b_1 \left| \left(U_x^\delta\right)^* U_x^\delta \right| q_2, a_2, b_2 \right\rangle \\ &= \sum_{q_1', c_1, d_1} \sum_{q_2', c_2, d_2} \delta^*(q_1, \sigma_1, s_1, q_1', c_1, d_1) \delta(q_2, \sigma_2, s_2, q_2', c_2, d_2) \left\langle q_1', a_1 + c_1, b_1 + \mu(d_1) \mid q_2', a_2 + c_2, b_2 + \mu(d_2) \right\rangle. \end{aligned}$$

Here we have

$$\begin{aligned} &\left\langle q_1', a_1 + c_1, b_1 + \mu(d_1) \mid q_2', a_2 + c_2, b_2 + \mu(d_2) \right\rangle \\ &\quad = \begin{cases} 1 & q_1' = q_2', a_1 + c_1 = a_2 + c_2, b_1 + \mu(d_1) = b_2 + \mu(d_2), \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

It follows that the inner product is

$$\langle q_1, a_1, b_1 \mid q_2, a_2, b_2\rangle = \sum_{\substack{q' \\ a_1 + c_1 = a_2 + c_2 \\ b_1 + \mu(d_1) = b_2 + \mu(d_2)}} \delta^*(q_1, \sigma_1, s_1, q', c_1, d_1) \delta(q_2, \sigma_2, s_2, q', c_2, d_2). \tag{14}$$

1. In the case $a_1 = a_2$ and $b_1 = b_2$, left hand side of (14) $= 1$ if $q_1 = q_2$ and 0 otherwise. Thus δ satisfies (1).
2. In the case $a_1 = a_2$ and $b_1 = b_2 \pm 1$, left hand side of (14) $= 0$. Thus δ satisfies (2).
3. In the case $a_1 = a_2$ and $b_1 = b_2 \pm 2$, left hand side of (14) $= 0$. Thus δ satisfies (3).
4. In the case $a_1 = a_2 \pm 1$ and $b_1 = b_2$, left hand side of (14) $= 0$. Thus δ satisfies (4).

5. In the case $a_1 = a_2 \pm 1$ and $b_1 = b_2 \pm 1$, left hand side of (14) = 0. Thus δ satisfies (5).
6. In the case $a_1 = a_2 \pm 1$ and $b_1 = b_2 \mp 1$, left hand side of (14) = 0. Thus δ satisfies (6).
7. In the case $a_1 = a_2 \pm 1$ and $b_1 = b_2 \pm 2$, left hand side of (14) = 0. Thus δ satisfies (7).
8. In the case $a_1 = a_2 \pm 1$ and $b_1 = b_2 \mp 2$, left hand side of (14) = 0. Thus δ satisfies (8).
9. In the case $a_1 = a_2 \pm 2$ and $b_1 = b_2$, left hand side of (14) = 0. Thus δ satisfies (9).
10. In the case $a_1 = a_2 \pm 2$ and $b_1 = b_2 \pm 1$, left hand side of (14) = 0. Thus δ satisfies (10).
11. In the case $a_1 = a_2 \pm 2$ and $b_1 = b_2 \mp 1$, left hand side of (14) = 0. Thus δ satisfies (11).
12. In the case $a_1 = a_2 \pm 2$ and $b_1 = b_2 \pm 2$, left hand side of (14) = 0. Thus δ satisfies (12).
13. In the case $a_1 = a_2 \pm 2$ and $b_1 = b_2 \mp 2$, left hand side of (14) = 0. Thus δ satisfies (13).
14. In the case $|a_1 - a_2| > 2$ or $|b_1 - b_2| > 2$, left hand side of (14) = 0. Since two quantum states are always different from each other, right hand side of (14) = 0. Thus, in this case, the equation (14) always holds.

From these, we conclude that, if U_x^δ is a unitary operator δ satisfies the well-formedness conditions.

On the other hand, if we assume that δ satisfies the well-formedness conditions, then we can easily check $\left(U_x^\delta\right)^* U_x^\delta = I$, that is, U_x^δ is a unitary operator. □

2.2 Simple 2Q1CAs

To describe automata easily, we introduce the concept of simple 2Q1CAs. First we introduce *counter-simple 2Q1CAs*.

Definition 6 *A 2Q1CA* $(Q, \Sigma, \delta, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}})$ *is counter-simple, if there are linear operators* $\{V_{\sigma,s}\}$ *on* $l_2(Q)$ *and a counter function* $C : Q \times \Gamma \to \{-1, 0, +1\}$ *such that for any* $q, q' \in Q$, $\sigma \in \Gamma$, $s \in \{0, 1\}$, $c \in \{-1, 0, +1\}$, $d \in \{\leftarrow, \downarrow, \rightarrow\}$,

$$\delta(q, \sigma, s, q', c, d) = \begin{cases} \langle q'| V_{\sigma,s} |q\rangle & C(q', \sigma) = c, \\ 0 & \text{otherwise}, \end{cases}$$

where $\langle q'| V_{\sigma,s} |q\rangle$ *is the coefficient of* $|q'\rangle$ *in* $V_{\sigma,s} |q\rangle$.

In this case, increase or decrease of the counter value is determined by the new state and the symbol it reads. Thus the 2Q1CA satisfies the conditions (4), (5), (9) automatically.

Next we introduce *head-simple 2Q1CAs*.

Definition 7 *A 2Q1CA* $(Q, \Sigma, \delta, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}})$ *is head-simple, if there are linear operators* $\{V_{\sigma,s}\}$ *on* $l_2(Q)$ *and a head function* $D : Q \to \{\leftarrow, \downarrow, \rightarrow\}$ *such that for any* $q, q' \in Q$, $\sigma \in \Gamma$, $s \in \{0, 1\}$, $c \in \{-1, 0, +1\}$, $d \in \{\leftarrow, \downarrow, \rightarrow\}$,

$$\delta(q, \sigma, s, q', c, d) = \begin{cases} \langle q'| V_{\sigma,s} |q\rangle & D(q') = d, \\ 0 & \text{otherwise}. \end{cases}$$

In this case, the tape head move is determined by the new state. Thus the 2Q1CA satisfies the conditions (2), (3), (5), (6), (7), (8), (10), (11), (12), (13) automatically.

Finally we introduce *simple 2Q1CAs* combining the concepts of counter-simple 2Q1CAs and head-simple 2Q1CAs.

Definition 8 *A 2Q1CA* $(Q, \Sigma, \delta, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}})$ *is simple, if there are linear operators* $\{V_{\sigma,s}\}$ *on* $l_2(Q)$*, a counter function* $C : Q \times \Gamma \to \{-1, 0, +1\}$ *and a head function* $D : Q \to \{\leftarrow, \downarrow, \rightarrow\}$ *such that for any* $q, q' \in Q$*,* $\sigma \in \Gamma$*,* $s \in \{0, 1\}$*,* $c \in \{-1, 0, +1\}$*,* $d \in \{\leftarrow, \downarrow, \rightarrow\}$*,*

$$\delta(q, \sigma, s, q', c, d) = \begin{cases} \langle q' | V_{\sigma,s} | q \rangle & C(q', \sigma) = c, D(q') = d, \\ 0 & \text{otherwise.} \end{cases}$$

In this case, increase or decrease of the counter value is determined by the new state and the symbol it reads, and the head move is determined by the new state. Thus the 2Q1CA satisfies the conditions (2)–(13) automatically.

Notice that the transition function of 2D1CAs can also be written as $\delta : Q \times \Gamma \times S \times Q \times \{-1, 0, +1\} \times \{\leftarrow, \downarrow, \rightarrow\} \to \{0, 1\}$, that is,

$$\delta(q, \sigma, s) = (q', c, d) \quad \Leftrightarrow \quad \delta(q, \sigma, s, q', c', d') = \begin{cases} 1 & (c', d') = (c, d), \\ 0 & (c', d') \neq (c, d). \end{cases}$$

Thus we can also define simple 2D1CAs in the way similar to simple 2Q1CAs.

Lemma 9 *A simple 2Q1CA satisfies the well-formedness conditions if there are unitary operators* $\{V_{\sigma,s}\}$ *such that for any* $\sigma \in \Gamma$ *and* $s \in \{0, 1\}$*,*

$$\sum_{q'} \langle q' | V_{\sigma,s} | q_1 \rangle^* \langle q' | V_{\sigma,s} | q_2 \rangle = \begin{cases} 1 & q_1 = q_2, \\ 0 & q_1 \neq q_2. \end{cases} \tag{15}$$

Proof. By the definition of simple 2Q1CAs, the well-formedness conditions except for (1) are satisfied automatically.

Now, we let

$$\begin{aligned} \delta(q_1, \sigma, s, q', c, d) &= \begin{cases} \langle q' | V_{\sigma,s} | q_1 \rangle & c = C(q', \sigma), d = D(q'), \\ 0 & \text{otherwise,} \end{cases} \\ \delta(q_2, \sigma, s, q', c, d) &= \begin{cases} \langle q' | V_{\sigma,s} | q_2 \rangle & c = C(q', \sigma), d = D(q'), \\ 0 & \text{otherwise,} \end{cases} \end{aligned}$$

then it is trivial to show that a simple 2Q1CA satisfies (1) if it satisfies (15). □

3 Reversible Simulation of 2D1CAs

In this section, we show that an arbitrary 2D1CA is simulated by a 2R1CA (which is viewed as a special case of 2Q1CA by its definition). To make the reversible simulation simpler, we show the following lemma.

Lemma 10 *For any language L which is recognized by a 2D1CA, there exists a simple 2D1CA which recognizes L and whose counter function does not depend on the symbol it reads.*

Proof. Let $M = (Q, \Sigma, \delta, q_0, Q_{\mathrm{acc}}, Q_{\mathrm{rej}})$ be a 2D1CA which recognizes L. Consider that M is in the state q' and there are transitions such that $\delta(q_1, \sigma_1, s_1) = (q', c_1, d_1), \delta(q_2, \sigma_2, s_2) = (q', c_2, d_2), (c_1, d_1) \neq (c_2, d_2)$. Since M is a 2D1CA, its previous state cannot be a superposition of q_1 and q_2. This means that we can distinguish q' reached by the transition $\delta(q_1, \sigma_1, s_1) = (q', c_1, d_1)$ from q' reached by the transition $\delta(q_2, \sigma_2, s_2) = (q', c_2, d_2)$.

We construct a simple 2D1CA for L as follows. Let the state sets

$$\begin{aligned} Q' &= \left\{ q^{c,d} \mid q \in Q, c \in \{-1,0,+1\}, d \in \{\leftarrow,\downarrow,\rightarrow\} \right\}, \\ Q'_{\text{acc}} &= \left\{ q^{c,d} \mid q \in Q_{\text{acc}}, c \in \{-1,0,+1\}, d \in \{\leftarrow,\downarrow,\rightarrow\} \right\}, \\ Q'_{\text{rej}} &= \left\{ q^{c,d} \mid q \in Q_{\text{rej}}, c \in \{-1,0,+1\}, d \in \{\leftarrow,\downarrow,\rightarrow\} \right\}. \end{aligned}$$

For each $q_1^{c_1,d_1}, q_2^{c_2,d_2} \in Q', \sigma \in \Gamma$, we define transition matrices $\{V'_{\sigma,s}\}$, a counter function C', and a head function D' as follows:

$$\begin{aligned} V'_{\sigma,s} \left| q_1^{c_1,d_1} \right\rangle &= q_2^{c_2,d_2} && \text{for } \delta(q_1,\sigma,s) = (q_2,c_2,d_2), \\ C'(q^{c,d},\sigma) &= c && \text{for any } \sigma \in \Gamma, \\ D'(q^{c,d}) &= d, \end{aligned}$$

and let the transition function δ' of M' be defined from given $V'_{\sigma,s}, C'$, and D'. Then $M' = (Q', \Sigma, \delta', q_0^{0,\downarrow}, Q'_{\text{acc}}, Q'_{\text{rej}})$ is a simple 2D1CA and by its construction we can easily check that M' simulates M and the counter function C' of M' does not depend on the symbol it reads. □

Notice that simple 2D1CAs cannot be more powerful than 2D1CAs by their definition. Therefore we have the following result.

Corollary 11 *Simple 2D1CAs are as powerful as 2D1CAs.*

Now we prove that an arbitrary 2D1CA is simulated by a simple 2R1CA (and hence by a simple 2Q1CA) by using the technique of reversible simulation. Kondacs and Watrous [15] showed that any two-way deterministic finite state automata can be simulated by two-way reversible finite state automata by using a technique due to Lange, McKenzie, and Tapp [17]. Our proof is an extension of the proof by Kondacs and Watrous [15] to one-counter cases.

Theorem 12 *For any language L which is recognized by a 2D1CA, there exists a simple 2R1CA which recognizes L.*

Proof. Let $M = (Q, \Sigma, \delta, q_0, Q_{\text{acc}}, Q_{\text{rej}})$ be a 2D1CA which recognizes L. From Lemma 10 we assume that M is a simple 2D1CA and its counter function does not depend on the symbol it reads. Given such an M, we define a 2R1CA $M' = \left(Q', \Sigma, \delta', q'_0, Q'_{\text{acc}}, Q'_{\text{rej}}\right)$ which recognizes L.

First, define

$$\begin{aligned} I_{q,\sigma,s} &= \left\{ q' \in Q \mid \delta(q',\sigma,s) = \delta(q,\sigma,s) \right\}, \\ J_{q,\sigma,s} &= \left\{ q' \in Q \mid \delta(q',\sigma,s) = q \right\}, \end{aligned}$$

and fix an ordering of the set Q. Let $\max(\cdot)$ and $\min(\cdot)$ denote the maximum and minimum functions relative to this ordering, and for any subset $R \subset Q'$, let $\operatorname{succ}(q, R)$ be the least element larger than $q \in R$.

Now we define M'. Let the state sets $Q' = Q \times \{-,+\}$, $Q'_{\text{acc}} = Q_{\text{acc}} \times \{-,+\}$, $Q'_{\text{rej}} = Q_{\text{acc}} \times \{-,+\}$, and let $q'_0 = (q_0, +)$. Also define the transition matrices $\{V'_{\sigma,s}\}$, the counter function C', and the head function D' of M' as follows.

For each $q \in Q, \sigma \in \Gamma$ for which $V_{\sigma,s}$ is defined in M,

$$V'_{\sigma,s} \left|(q,+)\right\rangle = \begin{cases} \left|\left(\operatorname{succ}(q, I_{q,\sigma,s}), -\right)\right\rangle & q \neq \max(I_{q,\sigma,s}), \\ \left|\left(V_{\sigma,s}\left|q\right\rangle, +\right)\right\rangle & q = \max(I_{q,\sigma,s}). \end{cases}$$

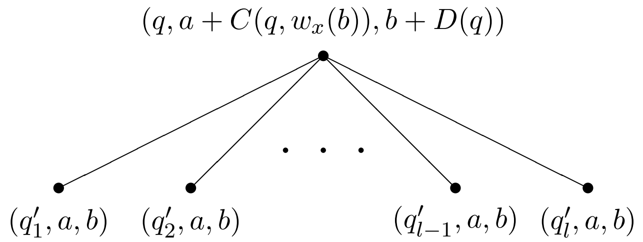

Figure 1: Vertex $(q, a + C(q, w_x(b)), b + \mu(D(q)))$ and its children

For each $q \in Q', \sigma \in \Gamma$,

$$V'_{\sigma,s}\,|q,-\rangle = \begin{cases} |(q,+)\rangle & J_{q,\sigma,s} = \emptyset, \\ \big|\big(\min(J_{q,\sigma,s}),-\big)\big\rangle & J_{q,\sigma,s} \neq \emptyset. \end{cases}$$

Define $C'\big((q,+),\sigma\big) = C(q,\sigma), C'\big((q,-),\sigma\big) = -C(q,\sigma)$, and $D'\big((q,+)\big) = D(q), D'\big((q,-)\big) = -D(q)$. Let the transition function δ' of M' be defined from given $V'_{\sigma,s}, C'$, and D'.

For given M and any input x of length n, let G be an undirected graph with set of vertices $Q' \times \mathbb{Z} \times [0, n+1]$, and edges between vertices (q_1, a, b) and $\big(q_2, a + C(q_2,\sigma), b + D(q_2)\big)$ if and only if $V_{w_x(b),\mathrm{sign}(a)}\,|q_1\rangle = q_2$. Let G_0 be the connected component of G which contains the initial configuration $\big((q_0,+),0,0\big)$. There can be no cycles in G_0, and G_0 must contain exactly one vertex corresponding to a halting state $\in Q_{\mathrm{acc}} \cup Q_{\mathrm{rej}}$. Thus we can view G_0 as a tree with the single halting configuration vertex as the root. M' simulates M by traversing G_0 in a reversible manner.

For each configuration (q, a, b) of M, there correspond two configurations $\big((q,+),a,b\big)$ and $\big((q,-), a - C(q,\sigma), b - \mu(D(q))\big)$ of M', which are to be interpreted as follows. Configuration $\big((q,+),a,b\big)$ indicates that the subtree of G_0 rooted at vertex (q,a,b) has just been traversed, and configuration $\big((q,-), a - C(q,\sigma), b - \mu(D(q))\big)$ indicates that the subtree of G_0 rooted at vertex (q,a,b) is now about to be traversed (here notice that C does not depend on σ).

Consider Figure 1. Here we have $J_{q,\sigma,s} = I_{q',\sigma,s} = \{q'_1, \dots, q'_l\}$ for each $i = 1, \dots, l$, where $\sigma = w_x(b)$ and $s = \mathrm{sign}(a)$. We assume that $q'_1 < \cdots < q'_l$ according to our ordering of Q'. Suppose that M' is in configuration $\big((q'_i,+),a,b\big)$ for $i < l$. Since $q'_i \neq \max(I_{q'_i,\sigma,s})$, the next configuration of M' is

$$\begin{aligned} &\Big(\big(\mathrm{succ}(q'_i, I_{q'_i,\sigma,s}),-\big), a + C'\big((\mathrm{succ}(q'_i, I_{q'_i,\sigma,s}),-),\sigma\big), b + \mu\big(D'\big((\mathrm{succ}(q'_i, I_{q'_i,\sigma,s}),-)\big)\big)\Big) \\ &\quad = \Big(\big(q'_{i+1},-\big), a - C(q'_i,\sigma), b - \mu(D(q'_i))\Big). \end{aligned}$$

Now suppose that M' is in configuration $\big((q'_l,+),a,b\big)$. Since $q'_i = \max(I_{q'_i,\sigma,s})$, the next configuration is

$$\Big(\big(V_{\sigma,s}\,|q'_l\rangle,+\big), a + C'\big((V_{\sigma,s}\,|q'_l\rangle,+),\sigma\big), b + \mu\big(D'\big((V_{\sigma,s}\,|q'_l\rangle,+)\big)\big)\Big) = \Big((q,+), a + C(q,\sigma), b + \mu(D(q))\Big).$$

Hence, M' enters configuration $\big((q,+), a + C(q,\sigma), b + \mu(D(q))\big)$ only after each of the subtrees rooted at its children have been traversed. Next, suppose that M' is in configuration $((q,-), a - C(q,\sigma), b - D(q))$. The next configuration of M' is

$$\begin{aligned} &\Big(\big(\min(J_{q,\sigma,s}),-\big), a - C(q,\sigma) + C'\big((\min(J_{q,\sigma,s}),-)\big), b - \mu(D(q)) + \mu\big(D'\big((\min(J_{q,\sigma,s}),-)\big)\big)\Big) \\ &\quad = \Big(\big(q'_1,-\big), a - C(q,\sigma) - C(q'_1,\sigma), b - \mu(D(q)) - \mu(D(q'_1))\Big), \end{aligned}$$

and so the subtree rooted at vertex $(q'_1, a - C(q,\sigma), b - \mu(D(q)))$ is now to be traversed. Finally, in the case that $\big(q, a + C(q,\sigma), b + \mu(D(q))\big)$ has no predecessors, we have $J_{q,\sigma,s} = \emptyset$, and so the configuration which immediately follows $\big((q,-),a,b\big)$ is $\big((q,+), a + C(q,\sigma), b + \mu(D(q))\big)$.

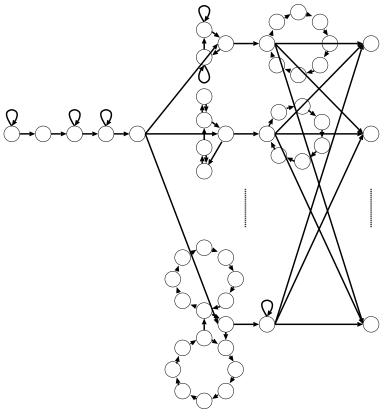

Figure 2: Transition image of M_{square}

By traversing G_0 in this manner, M' eventually enters one of the configurations in $Q'_{\text{acc}} \times \mathbb{Z} \times [0, n+1]$ or $Q'_{\text{rej}} \times \mathbb{Z} \times [0, n+1]$, and consequently accepts or rejects accordingly. It is clear that M' recognizes L since M recognizes L. $\square$

4 Recognizability

4.1 2Q1CA for $\{a^n b^{n^2} \mid n \geq 1\}$

Proposition 13 *Let L_{square} be $\{a^n b^{n^2} \mid n \geq 1\}$. For an arbitrary fixed positive integer $N \geq 2$, there exists a 2Q1CA M_{square}which accepts $x \in L_{\text{square}}$ with probability 1 and rejects $x \notin L_{\text{square}}$ with probability $1 - 1/N$. In either case, M_{square} halts after $O(N|x|)$ steps with certainty.*

Proof. Let $Q = \{q_0, q_1, q_2, q_3, q_4, q^i_{5,j_1}, q^i_{6,j_2}, q^i_7 \mid 1 \leq i \leq N, 1 \leq j_1 \leq i, 1 \leq j_2 \leq N-i+1\}$, $Q_{\text{acc}} = \{q^N_7\}$ and $Q_{\text{rej}} = \{q^j_7 \mid 1 \leq j \leq N-1\}$. For each $q \in Q$, $\sigma \in \Gamma$, $s \in \{0,1\}$, we define the transition matrices $\{V_{\sigma,s}\}$, the counter function C, and the head function D as follows:

$$\begin{array}{l} V_{¢,0}\left|q_0\right\rangle = \left|q_0\right\rangle \\ V_{¢,0}\left|q^i_{5,0}\right\rangle = \left|q^i_{6,N-i+1}\right\rangle \end{array}$$

$$\begin{array}{l} V_{\$,0}\left|q_2\right\rangle = \left|q_3\right\rangle \\ V_{\$,0}\left|q^i_{6,N-i+1}\right\rangle = \frac{1}{\sqrt{N}} \sum_{k=1}^{N} e^{\frac{2\pi i k}{N}\sqrt{-1}} \left|q^k_7\right\rangle \end{array}$$

$$\begin{array}{l} C(q^i_{5,2i}, a) = -1 \\ C(q^i_{5,i}, a) = +1 \\ C(q^i_{5,2i}, b) = -1 \\ C(q^i_{5,0}, a) = +1 \\ C(q, \sigma) = 0 \\ \quad \text{otherwise} \end{array} \qquad \begin{array}{ll} D(q_j) = \rightarrow & j = 0, 2, 4 \\ D(q_j) = \leftarrow & j = 1, 3 \\ D(q^i_{5,2i}) = \leftarrow & \\ D(q^i_{5,i}) = \rightarrow & \\ D(q^1_{6,N-i+1}) = \rightarrow & \\ D(q) = \downarrow & \text{otherwise} \end{array}$$

$$\begin{array}{l} V_{a,0}\left|q_0\right\rangle = \left|q_0\right\rangle \\ V_{a,0}\left|q_1\right\rangle = \left|q_2\right\rangle \\ V_{a,0}\left|q_3\right\rangle = \left|q_4\right\rangle \\ V_{a,s}\left|q^i_{5,j+1}\right\rangle = \left|q^i_{5,j}\right\rangle \\ \qquad j \neq 0, i \\ V_{a,0}\left|q^i_{5,i+1}\right\rangle = \left|q^i_{5,i}\right\rangle \\ V_{a,1}\left|q^i_{5,i+1}\right\rangle = \left|q^i_{5,2i}\right\rangle \\ V_{a,1}\left|q^i_{5,1}\right\rangle = \left|q^i_{5,i}\right\rangle \\ V_{a,0}\left|q^i_{6,j+1}\right\rangle = \left|q^i_{6,j}\right\rangle \\ \qquad 1 \leq j \leq N-i \\ V_{a,0}\left|q^i_{6,1}\right\rangle = \left|q^i_{6,N-i+1}\right\rangle \end{array}$$

$$\begin{array}{l} V_{b,0}\left|q_0\right\rangle = \left|q_1\right\rangle \\ V_{b,0}\left|q_2\right\rangle = \left|q_2\right\rangle \\ V_{b,0}\left|q_3\right\rangle = \left|q_3\right\rangle \\ V_{b,0}\left|q_4\right\rangle = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \left|q^i_{5,0}\right\rangle \\ V_{b,1}\left|q^i_{5,i}\right\rangle = \left|q^i_{5,0}\right\rangle \\ V_{b,1}\left|q^i_{5,0}\right\rangle = \left|q^i_{5,2i}\right\rangle \\ V_{b,0}\left|q^i_{6,j+1}\right\rangle = \left|q^i_{6,j}\right\rangle \\ V_{b,0}\left|q^i_{6,1}\right\rangle = \left|q^i_{6,N-i+1}\right\rangle \end{array}$$

By the construction of M_{square}, we see that the computation consists of three phases. The first phase rejects any input not of the form a^+b^+. This phase is straightforward, similar to 2-way reversible finite automata (with no-counter) which recognizes the input of the form a^+b^+. If the input is not of the form a^+b^+, the computation terminates and rejects. Otherwise, the second phase begins with the state q_4 with the tape head reading the left-most b.

At the start of the second phase, the computation branches into N paths, indicated by the states $q^1_{5,0}, \ldots, q^N_{5,0}$, each with amplitude $1/\sqrt{N}$. For each of these paths, M_{square} moves the tape head to left and right deterministically in the following way. Along the ith path, while the counter value is not 0, the automaton decreases the counter value by 1 and moves the tape head to left. In addition, every time the tape head reads the symbol a, it remains stationary for i steps. Upon the counter value being 0, it repeats the followings until the tape head reads the left-most b: it increases the counter value by 1 and moves the tape head to right. If the tape head reads the symbol ¢, the computation enters the third phase with the state $q^i_{5,0}$. Thus, while M_{square} is scanning a's in the input during the second phase, the tape head requires precisely

$$(i+1)\left(\sum_{c=0}^{m-1}(2c+1)+m\right)=(i+1)\left(m^2+m\right)$$

steps along the ith path, where m is the number of a's.

Along the ith path on the third phase, if the tape head reads the symbol a or b then it remains stationary for $N-i+1$ steps and after that moves to right. Upon reading the symbol \$, each computation path again splits according to the Discrete-Fourier Transformation, yielding the single accepting state q^N_7 and the other rejecting states $q^i_7 (1\le i\le N-1)$. Thus, while the automaton is scanning a's and b's in the input, the tape head requires precisely $(N-i+1)(m+n)$ steps along the ith path, where n is the number of b's. Therefore, it is easy to see that, under the assumption $i\neq i'$, $(i+1)\left(m^2+m\right)+(N-i+1)(m+n)=(i'+1)\left(m^2+m\right)+(N-i'+1)(m+n)$ if and only if $m^2=n$.

First consider the case that $m^2=n$. Since each of the N computation paths reaches the symbol \$ at the same time, the superposition immediately after performing the Discrete-Fourier Transformation is

$$\frac{1}{N}\sum_{i=1}^{N}\sum_{k=1}^{N}e^{\frac{2\pi ik}{N}\sqrt{-1}}\left|q^k_7\right\rangle=\left|q^N_7\right\rangle.$$

Hence, the accepting state q^N_7 is entered with probability 1.

Next suppose that $m^2\neq n$. In this case, each of N computation paths reaches the symbol \$ at a different timing. Thus, there is no cancellation among the rejection states. For each of N paths, the conditional probability that an observation results in q^N_7 at the time is $1/N$. It follows that the total probability that an observation results in q^N_7 is also $1/N$. Consequently the input is rejected with probability $1-1/N$.

We clearly see that each possible computation path has length $O(N|x|)$, since each path terminates in a halting states with certainty. ☐

4.2 2Q1CA for $\{a^mb^nc^{mn}\mid m,n\ge 1\}$

Proposition 14 *Let L_{prod} be $\{a^mb^nc^{mn}\mid m,n\ge 1\}$. For an arbitrary fixed positive integer $N\ge 2$, there exists a 2Q1CA M_{prod} which accepts $x\in L_{\text{prod}}$ with probability 1 and rejects $x\notin L_{\text{prod}}$ with probability $1-1/N$. In either case, M_{prod} halts after $O(N|x|)$ steps with certainty.*

Proof. Let $Q=\{q_0,q_1,q_2,q_3,q_4,q_5,q^i_6,q^i_7,q^i_{8,j_1},q^i_9,q^i_{10,j_2},q^i_{11}\mid 1\le i\le N, 1\le j_1,\le i, 1\le j_2\le N-i+1\}$, $Q_{\text{acc}}=\{q^N_{11}\}$ and $Q_{\text{rej}}=\{q^j_{11}\mid 1\le j\le N-1\}$. For each $q\in Q$, $\sigma\in\Gamma$, $s\in\{0,1\}$, we define the transition matrices $\{V_{\sigma,s}\}$, the counter function C and the head function D as follows:

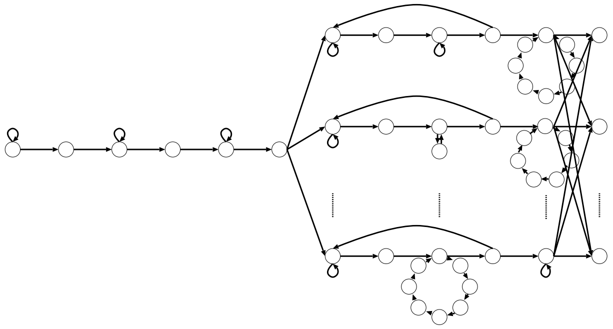

Figure 3: Transition image of $M_{\rm prod}$

$$V_{\text{¢},0}\left|q_0\right\rangle = \left|q_0\right\rangle$$
$$V_{\text{¢},0}\left|q_5\right\rangle = \frac{1}{\sqrt{N}}\sum_{i=1}^{N}\left|q_6^i\right\rangle$$
$$V_{\text{¢},1}\left|q_9^i\right\rangle = \left|q_6^i\right\rangle$$

$$V_{\$,0}\left|q_4\right\rangle = \left|q_5\right\rangle$$
$$V_{\$,0}\left|q_{10,1}^i\right\rangle = \frac{1}{\sqrt{N}}\sum_{k=1}^{N} e^{\frac{2\pi ik}{N}\sqrt{-1}}\left|q_{11}^k\right\rangle$$

$$C(q_6^i, a) = +1$$
$$C(q_9^i, a) = -1$$
$$C(q_9^i, c) = -1$$
$$C(q, \sigma) = 0 \quad \text{otherwise}$$

$$D(q_j) = \rightarrow \quad j = 0, 2, 4$$
$$D(q_j) = \leftarrow \quad j = 1, 3, 5$$
$$D(q_6^i) = \rightarrow$$

$$V_{a,0}\left|q_0\right\rangle = \left|q_0\right\rangle$$
$$V_{a,0}\left|q_1\right\rangle = \left|q_2\right\rangle$$
$$V_{a,0}\left|q_5\right\rangle = \left|q_5\right\rangle$$
$$V_{a,s}\left|q_6^i\right\rangle = \left|q_6^i\right\rangle$$
$$V_{a,s}\left|q_9^i\right\rangle = \left|q_9^i\right\rangle$$
$$V_{a,1}\left|q_7^i\right\rangle = \left|q_{8,1}^i\right\rangle$$

$$D(q_7^i) = \leftarrow$$
$$D(q_{8,1}^i) = \rightarrow$$
$$D(q_9^i) = \leftarrow$$
$$D(q_{10}^i) = \rightarrow$$
$$D(q) = \downarrow \quad \text{otherwise}$$

$$V_{b,0}\left|q_0\right\rangle = \left|q_1\right\rangle$$
$$V_{b,0}\left|q_2\right\rangle = \left|q_2\right\rangle$$
$$V_{b,0}\left|q_3\right\rangle = \left|q_4\right\rangle$$
$$V_{b,0}\left|q_5\right\rangle = \left|q_5\right\rangle$$
$$V_{b,0}\left|q_9^i\right\rangle = \left|q_{10,1}^i\right\rangle$$
$$V_{b,1}\left|q_6^i\right\rangle = \left|q_7^i\right\rangle$$
$$V_{b,1}\left|q_{8,j}^i\right\rangle = \left|q_{8,j+1}^i\right\rangle \quad 1 \le j \le i-1$$
$$V_{b,1}\left|q_{8,i}^i\right\rangle = \left|q_{8,1}^i\right\rangle$$
$$V_{b,1}\left|q_9^i\right\rangle = \left|q_9^i\right\rangle$$

$$V_{c,0}\left|q_2\right\rangle = \left|q_3\right\rangle$$
$$V_{c,0}\left|q_4\right\rangle = \left|q_4\right\rangle$$
$$V_{c,0}\left|q_5\right\rangle = \left|q_5\right\rangle$$
$$V_{c,0}\left|q_{10,j}^i\right\rangle = \left|q_{10,j+1}^i\right\rangle \quad 1 \le j \le N-i$$
$$V_{c,0}\left|q_{10,N-i+1}^i\right\rangle = \left|q_{10,1}^i\right\rangle$$
$$V_{c,1}\left|q_{8,1}^i\right\rangle = \left|q_9^i\right\rangle$$

By the construction of the automaton, we see that the computation consists of four phases. The first phase rejects any input not of the form $a^+b^+c^+$. This phase is straightforward, similar to 2-way reversible finite automata (with no-counter) which recognizes the input of the form $a^+b^+c^+$. If the input is not of the indicated form, the computation terminates. Otherwise, the second phase begins with the state q_5 with the tape head reading the symbol ¢.

At the start of the second phase, the computation branches into N paths, indicated by the states $q_6^1, \ldots, q_6^N$, each with amplitude $1/\sqrt{N}$. For each of these paths, the automaton moves the tape head to right and increases the counter value by 1 while reading the symbol a. Upon reading the symbol b, the third phase begins with the state q_8^i.

Along the ith path on the third phase, if the tape head reads the symbol b then it remains stationary for i steps and after that moves to right. After reading the symbol c, if the counter value is 0, the fourth phase begins with the state q_{10}^i. Otherwise repeat the followings until the tape head reaches the symbol ¢. While reading the symbol b, the automaton moves the tape head to left. While reading the symbol a, the automaton moves the tape head to left and decreases the counter value by 1. Upon reading the symbol ¢, the automaton re-enters the second phase. Thus, the tape head requires precisely m steps on each second phase and $in + m + n$ steps along the ith path on each third phase. It is easy to see that the automaton repeats the second and the third phase m times.

Along the ith path on the fourth phase, if the tape head reads the symbol c then it remains stationary for $N - i + 1$ steps and after that moves to right. Upon reading the symbol \$, each computation path again splits according to the Discrete-Fourier Transformation, yielding the single accepting state q_{11}^N and the other rejecting states $q_{11}^i (1 \le i \le N-1)$. Thus, the tape head requires precisely $(N - i + 1)l$ steps along the ith path, where l is the number of c's.

Therefore, it is easy to see that, under assumption $i \ne i'$, $2m^2 + (i+1)mn + (N-i+1)l = 2m^2 + (i'+1)mn + (N-i'+1)l$ if and only if $l = mn$.

First consider the case that $l = mn$. Since each of the N computation paths reaches the symbol \$ at the same time, the superposition immediately after performing the Discrete-Fourier Transformation is

$$\frac{1}{N}\sum_{i=1}^{N}\sum_{k=1}^{N} e^{\frac{2\pi ik}{N}\sqrt{-1}}\left|q_{11}^{k}\right\rangle = \left|q_{11}^{N}\right\rangle .$$

Hence, the accepting state q_{11}^{N} is entered with probability 1.

Next suppose that $l \neq mn$. In this case, each of N computation paths reaches the symbol \$ at a different timing. Thus, there is no cancellation among the rejection states. For each of N paths, the conditional probability that an observation results in q_{11}^{N} at the time is $1/N$. It follows that the total probability that an observation results in q_{11}^{N} is also $1/N$. Consequently the input is rejected with probability $1 - 1/N$.

We clearly see that each possible computation path has length $O(N|x|)$, since each path terminates in a halting states with certainty. $\square$

4.3 2Q1CA for $\{a_1^{n^1} a_2^{n^2} \dots a_k^{n^k} \mid n \geq 1\}$

Proposition 15 *For each fixed* $k \geq 1$, *there exists a 2Q1CA which recognizes* $\{a_1^{n^1} a_2^{n^2} \dots a_k^{n^k} \mid n \geq 1\}$.

Proof (Sketch). In the case $k = 1$, it is trivial. In the case $k = 2$, we proved in Proposition 13. Consider the case $k \geq 3$. First, the automaton checks whether the input is of the form $a_1^+ a_2^+ \dots a_k^+$. Next, the automaton checks whether $m_1^2 = m_2$ or not, where $m_j (1 \leq j \leq k)$ is the length of a_j's. Finally, it checks whether $m_1 m_j = m_{j+1} \ \ (2 \leq j \leq k-1)$ or not. $\square$

4.4 2Q1CA for $\{a^n b^{2^n} \mid n \geq 1\}$

Lemma 16 *There exists a 2R1CA* $M_{b^{2^n}}$ *which recognizes* $\{b^{2^n} \mid n \geq 0\}$.

Proof. Let the state set $Q = \{q_0, q_1, q_2, q_3, q_4, q_5, q_6, q_7, q_8\}$, $Q_{\mathrm{acc}} = \{q_7\}$ and $Q_{\mathrm{rej}} = \{q_8\}$. For each $q \in Q$, $\sigma \in \Gamma$, $s \in \{0, 1\}$, we define the transition matrices $\{V_{\sigma,s}\}$, the counter function C, and the head function D as follows:

$$\begin{array}{lll}
V_{\text{¢},0}\left|q_0\right\rangle = \left|q_0\right\rangle , & V_{\$,0}\left|q_0\right\rangle = \left|q_1\right\rangle , & V_{b,0}\left|q_0\right\rangle = \left|q_0\right\rangle , \\
V_{\text{¢},0}\left|q_3\right\rangle = \left|q_7\right\rangle , & V_{\$,1}\left|q_1\right\rangle = \left|q_2\right\rangle , & V_{b,0}\left|q_2\right\rangle = \left|q_3\right\rangle , \\
V_{\text{¢},s}\left|q_2\right\rangle = \left|q_8\right\rangle , & V_{\$,1}\left|q_6\right\rangle = \left|q_1\right\rangle , & V_{b,0}\left|q_3\right\rangle = \left|q_4\right\rangle , \\
 & & V_{b,0}\left|q_4\right\rangle = \left|q_6\right\rangle , \\
C(q_1, \$) = +1, & D(q_0) = \rightarrow, & V_{b,1}\left|q_2\right\rangle = \left|q_2\right\rangle , \\
C(q_2, \$) = +1, & D(q_2) = \leftarrow, & V_{b,1}\left|q_5\right\rangle = \left|q_6\right\rangle , \\
C(q_2, b) = -1, & D(q_3) = \leftarrow, & V_{b,1}\left|q_6\right\rangle = \left|q_5\right\rangle , \\
C(q_5, b) = +1, & D(q_4) = \rightarrow, & \\
C(q_6, b) = +1, & D(q_6) = \rightarrow, & \\
C(q, \sigma) = 0 \quad \text{otherwise}, & D(q) = \downarrow \quad \text{otherwise}, &
\end{array}$$

Reversibility of this automaton can be checked easily. $\square$

Proposition 17 *Let* L_{power} *be* $\{a^n b^{2^n} \mid n \geq 1\}$. *For an arbitrary fixed positive integer* $N \geq 2$, *there exists a 2Q1CA* M_{power} *which accepts* $x \in L_{\mathrm{power}}$ *with probability* 1 *and rejects* $x \notin L_{\mathrm{power}}$ *with probability* $1 - 1/N$. *In either case,* M_{power} *halts after* $O(N|x|)$ *steps with certainty.*

Proof. We can construct M_{power} from $M_{b^{2^n}}$ constructed in the proof of Lemma 16 by using the technique of path branching. Its behavior is as follows.

First, the automaton checks whether the input is of the form a^+b^+. Second, the computation branches into N paths, each with amplitude $1/\sqrt{N}$. Along the ith path, the automaton checks whether the number of b's is a power of 2, behaving in the same manner as $M_{b^{2^n}}$ except that it remains stationary for $N-i+1$ steps every time the tape head reads the symbol \$. Third, if the tape head reads the symbol a, then it remains for i steps and after that moves to left. Finally, upon reading the symbol ¢, each computation path again splits according to the Discrete-Fourier Transformation, which yields the single accepting state and other rejecting states.

By the construction of the automaton, we can easily see that, for $x \in L_{\mathrm{power}}$, the accepting state is entered with probability 1, while for $x \notin L_{\mathrm{power}}$, the accepting state is entered with probability $1 - 1/N$. $\square$

5 Conclusion and Open Problems

In this paper, we gave the definition of 2Q1CAs and proved that 2Q1CAs is at least as powerful as 2D1CAs. We also proved that 2Q1CAs recognize non-context-free languages, such as $\{a^n b^{n^2} \mid n \geq 1\}$, $\{a^m b^n c^{mn} \mid m, n \geq 1\}$, $\{a^n b^{2^n} \mid n \geq 1\}$, and so on.

Since these languages do not seem to be recognized by 2D1CAs, our results may suggest that 2Q1CAs are more powerful than 2D1CAs.

As for two-counter cases, it is known that two-way deterministic two-counter automata (2D2CAs) can simulate deterministic Turing machines [18]. From the result of Deutsch [12], quantum Turing machines cannot be beyond the undecidability. Thus we can conclude that two-way quantum two-counter automata (2Q2CAs) are exactly as powerful as 2D2CAs in view of language recognition, since we have a reversible simulation of a 2D2CA by extending our technique of Theorem 12. This suggests the possibility that, even in the one-counter cases, 2Q1CAs are at most as powerful as 2D1CAs in view of language recognition. Thus it is actually open whether 2Q1CAs are *strictly* more powerful than 2D1CAs.

As for simple models, we proved that simple 2D1CAs are as powerful as 2D1CAs. However, it remains open whether simple 2Q1CAs are as powerful as 2Q1CAs or not.

Another interesting open problem is to determine whether there are non-context-sensitive languages that can be recognized by 2Q1CAs with bounded error.
